

Asymptomatic Spread

- Asymptomatic spread occurs when infected people don't have symptoms, but they can still spread germs to others without knowing.
- Asymptomatic spread can occur from infected people in two groups.

Group 1:

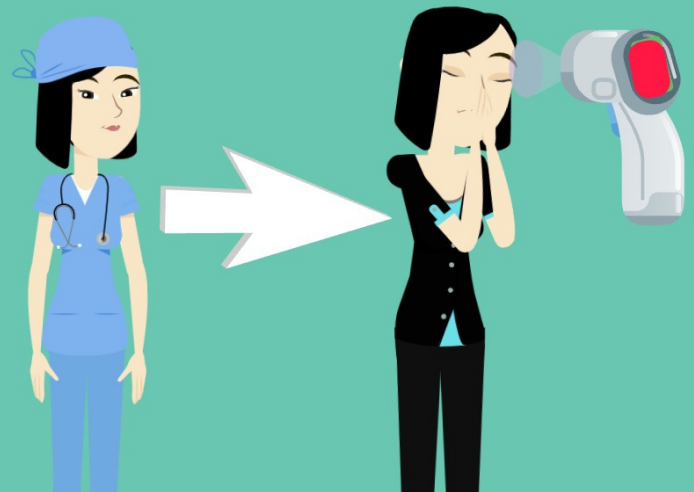

Never Experience Symptoms

- Do not have symptoms and feel good the entire time they're infected
- Usually never knows they are infected

Group 2:

Eventually Experience Symptoms

- Pre-symptomatic and are infected with germs that can spread to others before their symptoms start

Protect yourself and others by...

- washing your hands or using hand sanitizer when you touch your mouth and nose
- coughing into your elbow
- sneezing into a tissue
- wearing a mask if you have symptoms
- getting vaccinated

Germs can spread when people don't look or feel sick.
